AGILE PRESENTATION

By: Ryan Hatch

Roles in a Scrum Agile Team

01

Role 1 - Product Owner:

Definition: Responsible for maximizing the value of the product and managing the Product Backlog.

Importance: Serves as the liaison between the stakeholders and the development team.

Ensures that the team works on stories that deliver the most value to the business.

02

Role 2 - Scrum Master:

Definition: Acts as a servant leader and coach for the Scrum Team.

Importance: Facilitates Scrum events and helps the team adhere to Scrum practices.

Removes impediments that hinder the team's progress.

03

Role 3 - Development Team:

Definition: A group of professionals who do the work of delivering a potentially releasable increment of a finished product at the end of each Sprint.

Importance: Developers are cross-functional, with all the skills necessary to create a product increment and to collaborate on problem-solving and product development and product delivery.

Agile SDLC Phases

01

Phase 1 - Concept and Initiation:

Description: This is where the project's feasibility and business value are assessed.

Importance: Sets the foundation and direction for the project, ensuring alignment with business goals.

02

Phase 2 - Planning:

Description: Involves creating the product backlog, sprint planning, and release planning.

Importance: Ensures that the team has a clear understanding of the work to be done and priorities are set.

03

Phase 3 - Design and Development:

Description: This phase is iterative, with each sprint delivering a potentially shippable product increment.

Importance: Allows for flexibility and adaptability in developing features based on continuous feedback.

04

Phase 4 - Testing:

Description: Testing in Agile is continuous and often overlaps with development.

Importance: Ensures quality and functionality of the product through regular feedback and adjustments.

05

Phase 5 - Deployment:

Description: The product is delivered to the users, which can happen at the end of sprints or after several sprints.

Importance: Provides early and incremental value delivery to customers, aligning with business needs.

06

Phase 6 - Review and Maintenance:

Description: Post-deployment, the product is reviewed, and maintenance work is undertaken.

Importance: Ensures the product remains relevant and useful, with improvements and updates based on user feedback.

Waterfall vs. Agile: Process Differences

01

Waterfall Approach:

Nature: Sequential and linear, with each phase completed fully before moving to the next.

Example Scenario: In Waterfall, if a significant requirement change occurs during the development phase, the project must often cycle back to the beginning, redoing the requirements and design phases. This can cause delays and increased costs.

Challenge in Waterfall: Changes late in the project can be costly and time-consuming, as they may require revisiting and revising earlier stages.

02

Agile Approach:

Nature: Iterative and incremental, with continuous collaboration and feedback.

Example Scenario: In Agile, if new requirements emerge during development, they can be incorporated into the next sprint, allowing for flexibility and responsiveness without significant project delays.

Benefit in Agile: Agile accommodates changes more smoothly, allowing the project to adapt and evolve throughout the development process.

03

Comparative Analysis:

Waterfall: Best suited for projects with well-defined, unchanging requirements.

Agile: Ideal for projects where requirements are expected to change or evolve.

The Choice Between Waterfall and Agile

01

Project Requirements Stability:

Waterfall: I would rather consider to use waterfall if the project has well defined, stable requirements that are unlikely to change.

Agile: I would rather consider to use Agile if the project requirements are expected to evolve or are not fully clear at the outset.

02

Customer and Stakeholder Engagement:

Waterfall: For projects where customer involvement is limited to the beginning and end of the project.

Agile: Continuous customer feedback and involvement are necessary throughout the project.

03

Project Complexity and Size:

Waterfall: Works well for smaller, less complex projects with predictable outcomes.

Agile: Better suited for complex projects where the outcome is uncertain and innovation is key.

04

Risk Tolerance and Flexibility:

Waterfall: Good for projects where a structured approach is preferred and risks are well understood or at least minimal.

Agile: Favored when the project needs to be flexible to adapt to changing conditions and there's a higher tolerance for risk.
